

SPINNING REEL WITH CLICKING BAIL ARM

ABSTRACT OF THE DISCLOSURE

A bail securing apparatus secures a position of a bail. A plunger includes a first end and a second end. The first end applies a securing force against a bail support arm 5 supporting a first end of the bail. The first end of the plunger is slidably coupled with the second end by a compressible element forcing the first and second end apart. A plunger mount swivelably receives the second end. An elongated opening in the bail support arm receives the first end. The elongated opening having a longer dimension generally circumferentially aligned along a surface of the bail support arm such that when the bail 10 support arm is rotated between the first and second positions the compressible element forces the first end to slide along the elongated dimension of the elongated opening until the first end contacts a distal end of the elongated opening.
